# INVESTIGATION OF THE POSSIBLLITY OF POLYMERIZATION FOR THE $\mathrm{BeH}_{2}$ MOLECULE 

The Ground State of the $\mathrm{BeH}_{2}, \mathrm{Be}_{2} \mathrm{H}_{4}$ and $\mathrm{Be}_{3} \mathrm{H}_{6}$ Systems by the FSGO Method

By<br>I. TAMÁSSY-LENTEI and J. SZANISZLÓ<br>Institute of Theoretical Physics, Kossuth Lajos University, Debrecen

(Received July 1, 1974)

#### Abstract

Calculations were carried out for the ground state energy and equilibrium geometry of the $\mathrm{BeH}_{2}, \mathrm{Be}_{2} \mathrm{H}_{4}$ and $\mathrm{Be}_{3} \mathrm{H}_{6}$ molecules by the FSGO method. According to the investigations, the $\mathrm{BeH}_{2}$ molecule tends to have a polymerized form. The calculated dimerization and trimerization energy values are in good agreement with other calculated values available.

## Introduction

Nowadays the subject of quantum-mechanical and quantum-chemical studies shifts more and more towards the larger systems, the molecules. When a certain system is repeated several times, in principle many times, as a result of the increasing process or additional reaction, e.g. a chain-type compound will be formed. The polymerization process has been observed in many cases; an interesting possibility is that the polymer formation of beryllium-hidride, $\left(\mathrm{BeH}_{2}\right)_{n}$, is an existing polymer structure. The $\mathrm{BeH}_{2}$ molecule is a very simple one, but experimental data on its properties are actually not available. Since the experimental determination of the polymerization energy of the discrete $\mathrm{BeH}_{2}$ is not easy, therefore theoretical investigations have an increased importance.

The energy, the electronic and geometrical structure and other properties of a quantum-mechanical system may be determined by the solution of the Schrödinger equation. For small molecules there are many well treatable approximation methods producing precise results, but for larger systems we must content ourselves with the use of relatively simple methods. One of these is the FSGO (Floating Spherical Gaussian Orbital) method. The main advantage of its application is that it is an $a b$ initio method, without any empirical parameters, and it is very easy to determine the integrals necessary for the calculations; and on the other hand the computer demand of the method is not too large. It was Boys [1] who first proposed Gaussiantype one-electron orbitals centered on the nuclei. Then, to achieve better results,

Preuss [2] and others suggested to use floating-type (off-centre) spherical Gaussians having the form:

$$
\begin{equation*}
\psi_{i}=\left(2 / \pi \varrho_{i}^{2}\right)^{3 / 4} \exp \left[-\left(\mathbf{r}-\mathbf{R}_{i}\right)^{2} / e_{i}^{2}\right] \tag{1}
\end{equation*}
$$

as orbitals.
To determine the approximative wave-function of a system applying the variational method in the customary way, in (1) the orbital radii $\varrho_{i}$, but also the position vectors $\mathbf{R}_{i}$ have to be treated as variational parameters. In the FSGO method the wavefunction of a $2 n$-electron system for a singlet ground state is considered as a single Slater determinant composed from $n$ different double occupied one-electron spherical Gaussians.

Lately Frost [3] started an extensive computation series with this model to determine the total energy, equilibrium geometrical structure and other physical properties of some systems. Previously, the method proved to be well applicable among others for the description of interaction potentials of atoms and ions [4], for the calculation of proton affinities [5], for the determination of dissociation energies [6].

In the present paper we intend to apply the FSGO method for the investigation of the polymerization of the $\mathrm{BeH}_{2}$ molecule. Regarding the computational details, we refer e.g. to [5]. The calculations were carried out on the ODRA 1204 computer of the University Computer Center.

## The $\mathrm{BeH}_{2}$ system

The $\mathrm{BeH}_{2}$ is a very symmetrical molecule. Therefore it is natural to center one of the orbitals on the Be nucleus (inner shell orbital) with orbital radius $\varrho_{i n}$ and the other two on the BeH line, equidistant from the

Table I

| $R$ | 2.669 |
| $E(\mathrm{FSGO})$ | $-13.214^{*}$ |

* See Ref. [3(b)] Be (bonding orbitals) with orbital radii $\varrho_{B}$. The result of the variational calculation is, that the $\mathrm{BeH}_{2}$ is a linear molecule. So the $X$-axis was chosen as molecular axis, taking the Be atom as origin, and the co-ordinates of the bonding orbitals were denoted with $\pm X_{B}$. The results of the calculation (total energy $E$; equilibrium internuclear distance $R$ ) are summarized in Table I. (Atomic units are employed throughout.) Accordingly, the $\mathrm{BeH}_{2}$ is a stable system in the ground state, though this is not known from experiments.

## The $\mathrm{Be}_{2} \mathrm{H}_{4}$ system

The $\mathrm{Be}_{2} \mathrm{H}_{4}$ molecule was considered as a planar system, in the $X-Y$ plane. The two Be atoms were placed on the $X$-axis, being at the same time the molecular axis, and symmetrically to the origin, with co-ordinates $X_{\mathrm{Be}}$. Two H atoms were localized symmetrically to the $X$-axis, two others to the $Y$-axis with co-ordinates $X_{\mathrm{H}_{i}}, Y_{\mathrm{H}_{i}}(i=1,2,3,4)$, (see Fig. 1). Two inner orbitals were localized on the $X$-axis, near the Be atoms, at the points $P_{1}, P_{2}$, with co-ordinates $X_{1}, X_{2}$ and orbital radii
$\varrho_{1}, \varrho_{2}$. The four further bonding orbitals were placed close to the H atoms, in the points $P_{i}$, with co-ordinates $X_{i}, Y_{i}$; and orbital radii $\varrho_{i}(i=3,4,5,6)$; obviously two of them were always laid symmetrically to a co-ordinate-axis, namely, the bond bridge was assumed to be of rhomboid form. According to the calculations the

Fig. 1
two inner orbitals are centred practically on the Be atoms, two H atoms and two bonding orbitals are centred on the $X$-axis, and the other two on the $Y$-axis. The results for both cases are presented in Table II (in atomic units). Consequently, the experimentally unknown $\mathrm{Be}_{2} \mathrm{H}_{4}$ is more stable, than the configuration belonging to the separated $\mathrm{BeH}_{2}$ molecules.

Taking into account the geometry of the $\mathrm{Be}_{2} \mathrm{H}_{4}$ molecule, first the following molecular structure was supposed for the $\mathrm{Be}_{3} \mathrm{H}_{6}$ : The three Be atoms and two of

## The $\mathrm{Be}_{3} \mathrm{H}_{6}$ system

the H atoms $\left(\mathrm{H}_{1}, \mathrm{H}_{2}\right)$ were placed on the $X$-axis, which was chosen as the molecular axis (see Fig. 2a). Two other H atoms $\left(\mathrm{H}_{3}, \mathrm{H}_{4}\right)$ and two of the Be atoms $\left(\mathrm{Be}_{1}, \mathrm{Be}_{2}\right)$ were supposed to form a rhombus. The line connecting the $\mathrm{H}_{3}$ and $\mathrm{H}_{4}$ was considered

Fig. $2 a$
as parallel to the $Z$-axis. The plane of the other rhombus determined by the $\mathrm{Be}_{2}$, $\mathrm{Be}_{3}$, further by the $\mathrm{H}_{5}, \mathrm{H}_{6}$ was presumed to be orthogonal to the former one, so it is lying in the $Y-Z$ co-ordinate-plane. (We shall call this form a linear form.) One inner orbital was placed on the $\mathrm{Be}_{2}$ atom, at the origin. The other orbitals were

centred near the $\mathrm{Be}_{1}$ and $\mathrm{Be}_{3}$, at the points $P_{1}, P_{3}$ on the $X$-axis with co-ordinates $X_{1}, X_{3}$. According to the calculations, it was nearly unimportant, whether the $P_{1}$ resp. $P_{3}$ were kept fixed on the place of the $\mathrm{Be}_{1}$ resp. $\mathrm{Be}_{3}$ or not. Six bonding orbitals were centred on the connecting lines of the $\mathrm{Be}_{1}-\mathrm{H}_{1}, \mathrm{Be}_{3}-\mathrm{H}_{2}, \mathrm{H}_{3}-\mathrm{H}_{4}$ and $\mathrm{H}_{5}-\mathrm{H}_{6}$, near the H atoms, symmetrically. For both cases (inner shell orbitals centred on the Be atoms, or not) the results are collected in Table IIIa (in atomic units). The notations are used in quite similar sense as before.

Another possibility is to consider the $\mathrm{Be}_{3} \mathrm{H}_{6}$ as a system having cyclic planar molecular structure (see Fig. 2b). For reasons of symmetry the $\mathrm{Be}_{1}, \mathrm{Be}_{2}, \mathrm{Be}_{3}$; the $\mathrm{H}_{1}$, $\mathrm{H}_{2}, \mathrm{H}_{3}$ and the $\mathrm{H}_{4}, \mathrm{H}_{5}, \mathrm{H}_{6}$ atoms were placed on the same circles. Further the centres of the orbitals $P_{1}, P_{2}, P_{3}$, the $P_{\mathrm{B}_{1}}, P_{\mathrm{B}_{2}}, P_{\mathrm{B}_{3}}$ and the $P_{\mathrm{B}_{4}}, P_{\mathrm{B}_{5}}, P_{\mathrm{B}_{6}}$, were each also similary situated on circles. The variational procedure was carried out in such a way that the points $P_{1}, P_{2}, P_{3}$ coincided with the three Be atoms, or their co-ordinates were considered as variational parameters. The equivalent bond lengths and angles were assumed to be equal. The results obtained for both cases are collected in Table III $b$ (in atomic units). As it can be seen, although the cyclic structure for the $\mathrm{Be}_{3} \mathrm{H}_{6}$ is a stable one, but the linear form is energetically more favourable, so it is the more stable conformation.

## Discussion

In the last decade there are numerous theoretical calculations concerning the $\mathrm{BeH}_{2}$ systems dealt with here. Now the configuration interaction study of Hosteny and Hagstrom [7] can be regarded as the most accurate treatment with an optimized 80 -term wave-function. One can find further detailed references concerning the $\mathrm{BeH}_{2}$ in [7]. According to this very precise investigation, but also those of other authors, the $\mathrm{BeH}_{2}$ is a stable molecule. (This follows from the FSGO model
too, using the energetical data of the Be and $\mathrm{H}_{2}$ [5].) All the same, the system is unobservable because of unfavourable experimental conditions of measurement. Beside this it seems that the $\mathrm{BeH}_{2}$ has the property of polymerization. The experimental values of the polymerization energy of the $\mathrm{BeH}_{2}$ are uncertain, but the theoretical values can be estimated. It is rather easy to get the dimerization and trimerization energies as simple energy differences. Our calculated values are given in Table IV

Table IV

|  | FSGO | Theor.* |
| :--- | :---: | :---: |
| $E_{\text {dim }}($ dimerization energy $)=2 E\left(\mathrm{BeH}_{2}\right)-E\left(\mathrm{Be}_{2} \mathrm{H}_{4}\right)$ | 0.046 | 0.0445 resp. <br>  <br> $0.05 \pm 0.01^{* *}$ <br> $E_{\text {trim }}($ (trimerization energy $)=E\left(\mathrm{Be}_{2} \mathrm{H}_{4}\right)+E\left(\mathrm{BeH}_{2}\right)-$ <br> $-E\left(\mathrm{Be}_{3} \mathrm{H}_{6}\right)$ |

* Values from [8]
** Estimated value in [8]
(in atomic units). There are no experimental data available for comparison. The only theoretical study on this subject known by the authors is the recent computation of Ahlrichs [8]. This ab initio investigation, starting from an SCF calculation, includes the electron correlation energy of the valence shell electrons too. Our calculated values are in good agreement with the results mentioned above (see [8]). Accordingly, the very simple FSGO model seems to be appropriate to predict the existence of the tendency for polymerization in the investigated system.

It is possible to calculate the energy of the $\left(\mathrm{BeH}_{2}\right)_{n}$ linear polymer system for $n \leqq 4$, and the polymerization energy of polymers higher than the trimer, too. However, the computer requirements are significantly larger. It is probable that the polymerization energy generally has a value near 0.05 of order per molecule.
